Tidying Data tidyr

2/22/23

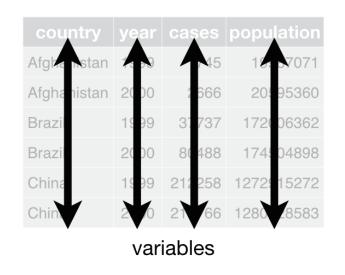

tidyr

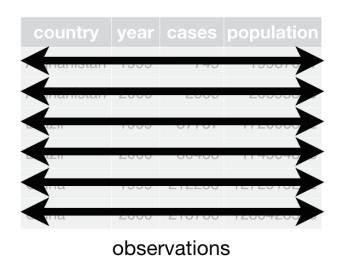

Functions for tidying data. What is tidy data?

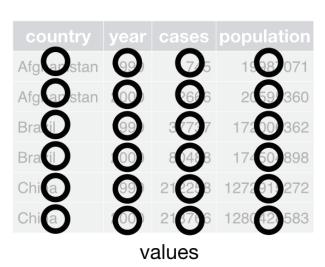

"Tidy datasets are all alike, but every messy dataset is messy in its own way." — Hadley Wickham

Tidy Data

Each column is a single variable

Each row is a single observation

Each cell is a value

pivot_longer()

```
1 pivot_longer(<DATA>, <NAMES TO>, <VALUES TO>, <VARIABLES>)
```

Lord of the Rings

```
lotr <- tribble(</pre>

new data alert!

table2, table4a, who

Where does it come from?

The tidyr R package

How can I use it?

library(tidyr)
 View(table2)
 View(table4a)
 View(who)

they're invisible!

Use pivot_longer() to reorganize table4a into three columns: country, year, and cases.

```
1 table4a |>
2  pivot_longer(
3    names_to = "year",
4    values_to = "cases",
5    cols = -country
6 )
```

```
# A tibble: 6 \times 3
 country year
                 cases
 <chr> <chr> <chr> <dbl>
1 Afghanistan 1999
                    745
2 Afghanistan 2000 2666
3 Brazil
            1999 37737
4 Brazil
            2000 80488
5 China
            1999 212258
6 China
            2000
                 213766
```

pivot_wider()

1 pivot_wider(<DATA>, <NAMES FROM>, <VALUES FROM>)

wide						
id	х	У	z			
1	a	С	е			
2	b	d	f			

wide

pivot_wider()

```
1 lotr |>
2  pivot_longer(
3    names_to = "sex",
4    values_to = "words",
5    cols = female:male
6  ) |>
7  pivot_wider(
8    names_from = race,
9    values_from = words
10  )
```

Use pivot_wider() to reorganize table2 into four columns: country, year, cases, and population.

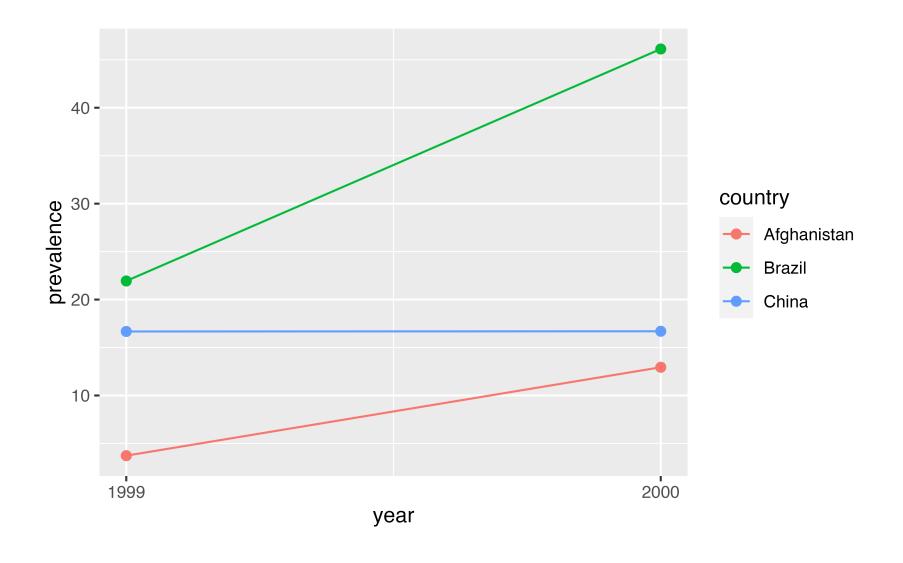

Create a new variable called prevalence that divides cases by population multiplied by 100000.

Pass the data frame to a ggplot. Make a scatter plot with year on the x axis and prevalence on the y axis. Set the color aesthetic (aes()) to country. Use size = 2 for the points. Add a line geom.

1 table2

```
country year cases population prevalence
 <chr> <dbl> <dbl>
                         <dbl>
                                 <dbl>
1 Afghanistan 1999 745 19987071
                                 3.73
2 Afghanistan 2000 2666 20595360
                                 12.9
3 Brazil 1999 37737 172006362
                                 21.9
4 Brazil 2000 80488 174504898
                                 46.1
5 China
           1999 212258 1272915272
                                 16.7
6 China
           2000 213766 1280428583
                                  16.7
```

```
1 table2 |>
2  pivot_wider(
3    names_from = type,
4   values_from = count
5  ) |>
6  mutate(prevalence = (cases / population) * 100000) |>
7  ggplot(aes(x = year, y = prevalence, color = country)) +
8  geom_point(size = 2) +
9  geom_line() +
10  scale_x_continuous(breaks = c(1999L, 2000L))
```

Pivot the 5th through 60th columns of who so that the names of the columns go into a new variable called codes and the values go into a new variable called n. Then select just the country, year, codes and n variables.

1 who

```
1 who |>
2    pivot_longer(
3         names_to = "codes",
4         values_to = "n",
5         cols = 5:60
6    ) |>
7         select(country, year, codes, n)
```

```
# A tibble: 405,440 \times 4
  country
               year codes
                                     n

                                    NA
   --<u>-</u>-----
```

separate()/unite()

Use the cases data below. Separate the sex_age column into sex and age columns.

```
1 cases <- tribble(
2    ~id,    ~sex_age,
3    "1",    "male_56",
4    "2",    "female_77",
5    "3",    "female_49"
6 )
7 separate(_____, ____, into = c("____", "___"))</pre>
```

```
# A tibble: 3 × 3
  id sex age
  <chr>      <chr>      <chr> 1 1 male 56
2 2 female 77
3 3 female 49
```

```
1 cases <- tribble(</pre>
   ~id, ~sex_age,
  "1", "male_56",
4 "2", "female_77",
5 "3", "female 49"
6
   separate(
   cases,
   sex age,
into = c("sex", "age"),
11 convert = TRUE
12 )
```

Your Turn 5: Challenge!

There are two CSV files in this folder containing SEER data in breast cancer incidence in white and black women. For both sets of data:

Import the data

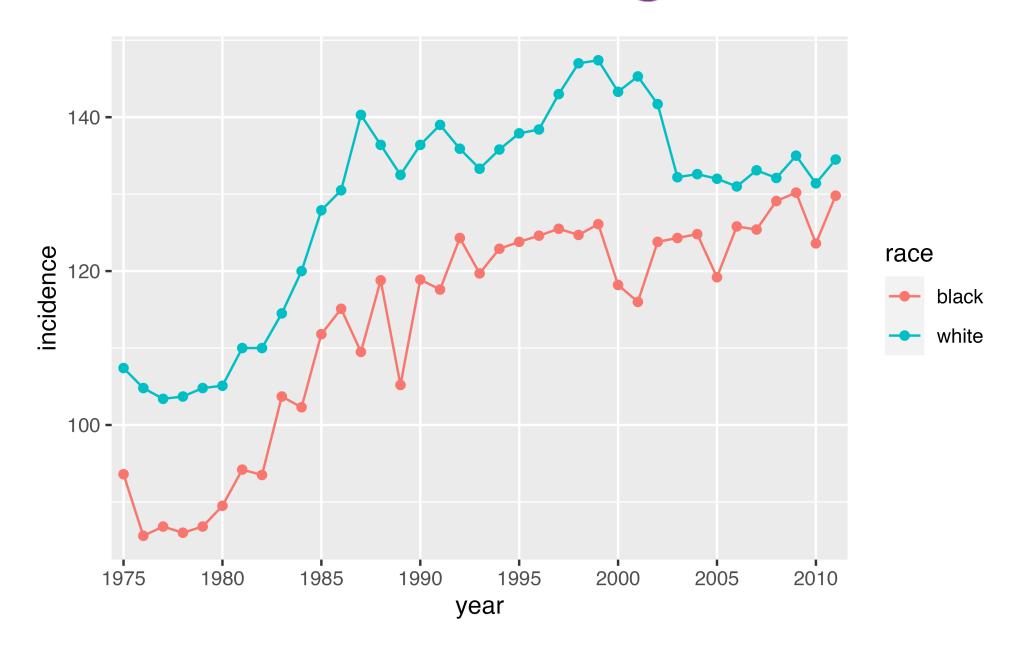

Pivot the columns into 2 new columns called year and incidence

Add a new variable called race. Remember that each data set corresponds to a single race.

Bind the data sets together using bind_rows() from the dplyr package. Either save it as a new object or pipe the result directly into the ggplot2 code.

Plot the data using the code below. Fill in the blanks to have year on the x-axis, incidence on the y-axis, and race as the color aesthetic.

Your Turn 5: No solution **Turn**

Other neat tidyr tools Uncounting frequency tables

```
1 lotr |>
2  pivot_longer(
3    names_to = "sex",
4    values_to = "count",
5    cols = c(female, male)
6  ) |>
7    uncount(count)
```

Other neat tidyr tools

```
# A tibble: 21,245 \times 3
   film
                               race
                                     sex
   <chr>
                               <chr> <chr>
                                     female
 1 The Fellowship Of The Ring Elf
                                     female
 2 The Fellowship Of The Ring Elf
 3 The Fellowship Of The Ring Elf
                                     female
 4 The Fellowship Of The Ring Elf
                                     female
                                     female
 5 The Fellowship Of The Ring Elf
 6 The Fellowship Of The Ring Elf
                                     female
                                     female
 7 The Fellowship Of The Ring Elf
 8 The Fellowship Of The Ring Elf
                                     female
 9 The Fellowship Of The Ring Elf
                                     female
10 The Fellowship Of The Ring Elf
                                     female
```

Other neat tidyr tools

Work with data frames

```
crossing() and expand()
nest() and unnest()
```

Other neat tidyr tools

Work with missing data

```
complete()
drop_na() and replace_na()
```
